# PDF chrome showcase

All four canonical chrome surfaces — **metadata**, **watermark**, **header / footer**, and **bookmarks** — wired through the same **DocumentSession** mutators every backend honours.

### Document metadata

Open this PDF in a viewer that shows **Document Properties** — title, author, subject, keywords, creator, and producer all flow from the canonical **DocumentMetadata** value.

### Watermark

The diagonal **DRAFT** watermark behind this paragraph is text-based — switch to image mode by configuring **imagePath** or **imageBytes** on the watermark builder. **BEHIND_CONTENT** sits behind the body; **OVER_CONTENT** paints on top.

### Header & footer

Top of every page carries the document title and the rendered **{date}** token; bottom carries **Page {page} of {pages}**. Both zones share the same **DocumentHeaderFooter** value type and accept independent fontSize / textColor / separator settings. The footer names **PT Sans** through **fontName** — its Cyrillic counter keeps its letters where the standard-14 default would substitute — and **reserveSpace(true)** keeps the body clear of the band.

### Bookmarks

Every **ParagraphBuilder.bookmark(...)** call materialises a PDF outline entry. Open the rendered PDF in a viewer with an outline panel to see **Chrome showcase** expand into Metadata, Watermark, Header & Footer, and Bookmarks sub-entries.

### Protection (not enabled in this PDF)

To encrypt the PDF, configure **DocumentSession.protect(DocumentProtection.builder()...)** with userPassword / ownerPassword / canPrint / canCopyContent / canModify / canFillForms / keyLength. This example skips the protect call so the rendered PDF stays readable without a password.

All five surfaces are renderer-neutral — DOCX honours metadata and node page zones; the text header/footer, watermark and bookmarks stay fixed-layout (PDF/PPTX).
