Shape-as-container

Compose a shape, place normal document nodes inside it, **and clip the children to the outline** while the whole unit paginates atomically.

A circle owns its label and clips by the ellipse path.

Nine-point anchors and offsets use the same vocabulary as LayerStack.

Feature card

Children are still **semantic nodes**: paragraphs, sections, badges, and rich text.

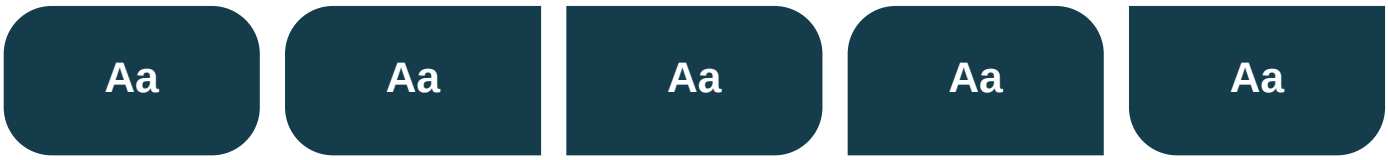
A rounded rectangle can host sections, rich text, and badge layers.

Clip policies

Default **CLIP_PATH** clips to the actual outline. **CLIP_BOUNDS** clips to the bounding box, and **OVERFLOW_VISIBLE** keeps child overflow visible for deliberate effects.

Per-corner radius

roundedRect(w, h, **DocumentCornerRadius.right(r)**) rounds corners independently — a card flush on one side, no CLIP_PATH parent.



of(r) left(r) right(r) top(r) bottom(r)

Vertical text seating

paragraph.**verticalAlign(TextVerticalAlign.TOP / CENTER / BOTTOM)** seats a single line by its cap band inside a taller shape — no lift offsets. **The gold line marks the box centre.**
